

Redux

- It is a JS library used to manage the state globally
- Technical terms to know while using redux
 1. reducer function
 2. action
 3. initialState

Slice

```
let globalState = {
  count:0
}

function reducer(oldstate=globalState,action){
  const newState = {...oldstate}
  if(action.type == 'counter/increment')
    newState.count+=action.payload
  else if(action.type == 'counter/decrement')
    newState-=action.payload

  return newState
}
```

```
const a1 = {
  type: 'counter/increment'
  payload:2
}

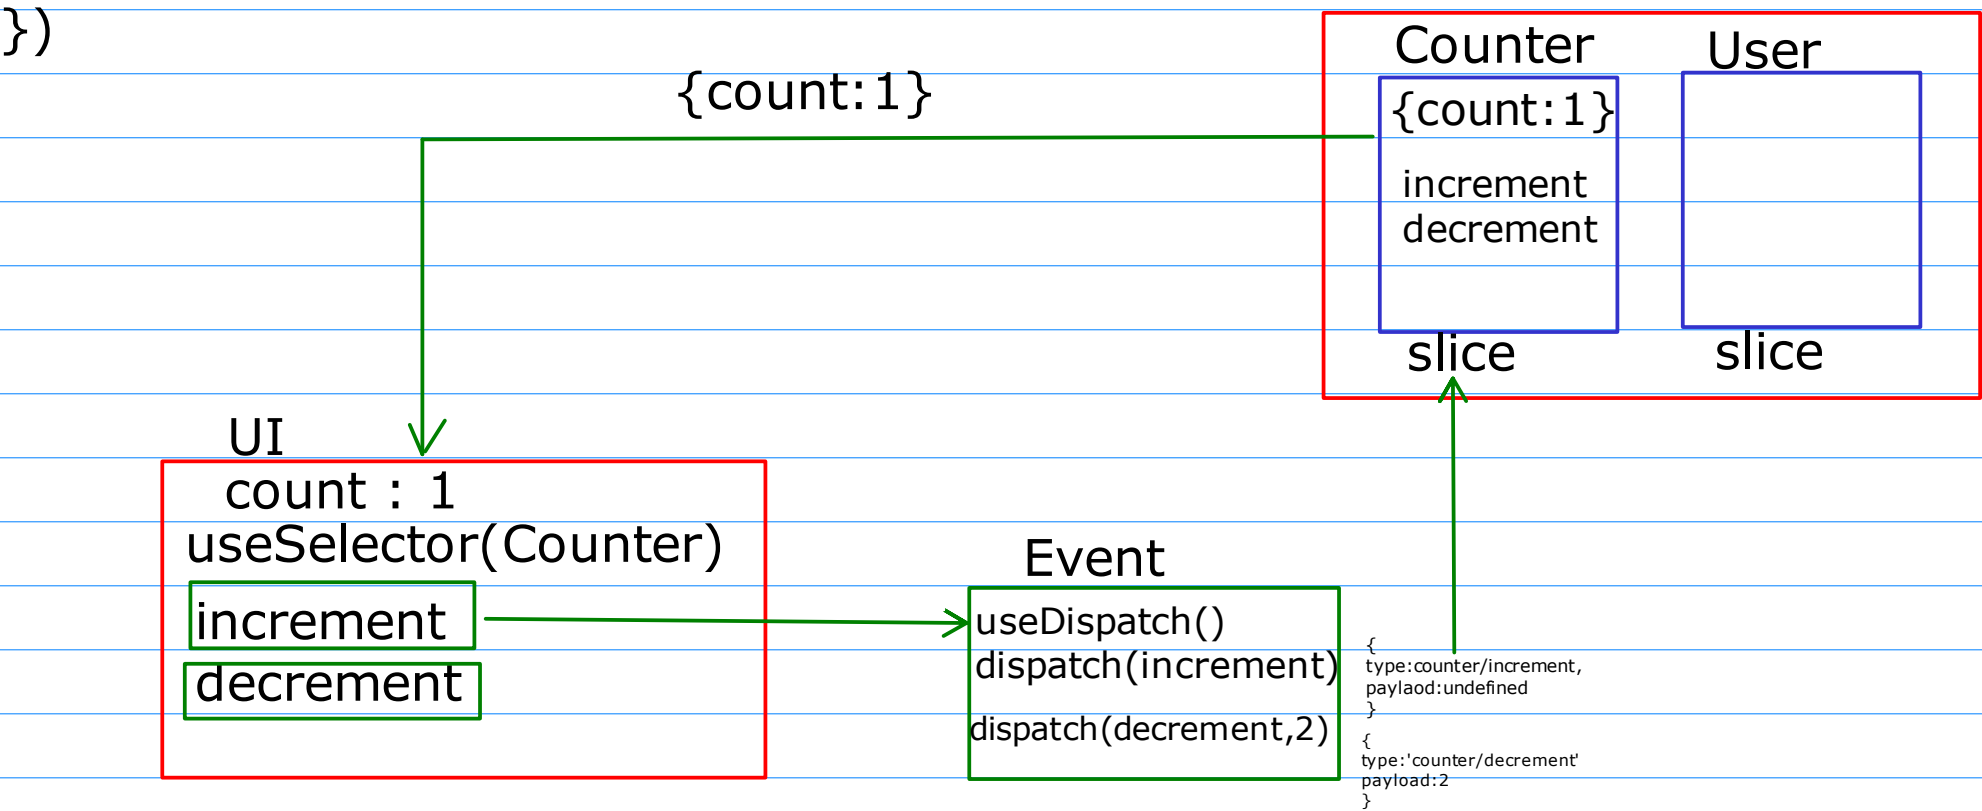

const a2 = {
  type : 'counter/decrement'
  payload : 1
}
```

```
globalState = reducer(globalState,a1)
globalState = reducer(globalState,a2)
=reducer()
```

```
const counterSlice= createSlice({
  name:counter,
  initialState = {
    count:0
  },
  reducers:{
    increment:(newState,action)=>{ } ,
    decrement:(newState,action)=>{ }
  }
})
```

// pass the configuration while creating the slice
// which internally will create global state
// and respective reducer function to manage the state

Store

To use the redux install 2 dependencies

1. npm install @reduxjs/toolkit

- It is the redux library that provides the functions to
 - a. create the slice and
 - b. configure the store

2. npm install react-redux

- It is a library used to bind the react application with the redux
- It provides 2 hooks
 - a. useSelector()
 - To choose the reducer function from which we need to get the state
 - b. useDispatch()
 - To create and dispatch an action object to the reducer function
